Abstract

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Etiam lobortis facilisis sem. Nullam nec mi et neque pharetra sollicitudin. Praesent imperdiet mi nec ante. Donec ullamcorper, felis non sodales commodo, lectus velit ultrices augue, a dignissim nibh lectus placerat pede. Vivamus nunc nunc, molestie ut, ultricies vel, semper in, velit. Ut porttitor. Praesent in sapien. Lorem ipsum dolor sit amet, consectetur adipiscing elit. Duis fringilla tristique neque. Sed interdum libero ut metus. Pellentesque placerat. Nam rutrum augue a leo. Morbi sed elit sit amet ante lobortis sollicitudin. Praesent blandit blandit mauris. Praesent lectus tellus, aliquet aliquam, luctus a, egestas a, turpis. Mauris lacinia lorem sit amet ipsum. Nunc quis urna dictum turpis accumsan semper.

I. INTRODUCTION

Earth has been orbiting the Sun for billions of years. Even with several hundred natural satellites in a complex scheme of orbits is our solar system a stable physical system. Although the system has been stable over a long time, it is convenient to simulate the system to understand how it will react in different situations. Simulations give also an useful source of information about the fundamentals of our solar system. This project will build a numerical solver based on the gravitational force between two massive objects in combination with Newton's second and third law of motion. The methods tested for the solver is Euler's method and the Verlet velocity method, both methods commonly used for solving differential equations. The solver will be controlled by solving simple systems and compared to analytical results before introduced to more advanced systems where analytical solutions are impossible to find. Further, relativistic corrections will be implemented in the simulator to reduce unwanted effects such as perihelion distortion. The physics and numer-

ical methods used in the project are described in more detail in section II. How these are combined into a simulator is described in section III, and the output from test and experiments are described in section IV. A summary of the most important findings are found in section V.

II. THEORY AND METHODS

i. Gravitational force

Newton published a formula for describing the gravitational force in 1687, which is still in use today. Where the gravitational force between two massive objects depends on the masses of the objects and the distance between them.

$$F_G = G \frac{M_A M_B}{r_{AB}^2} \quad (1)$$

The two masses M_A and M_B belongs to object A and B respectively and r_{AB} is the distance between them. G is a gravitational force constant, called `CONSTANT`. For objects in high speed or in a strong gravitational field, it is necessary to add a relativistic correction to the

classical force.

$$F_{G,relativistic} = F_G \left(1 + \frac{3|r \times v|^2}{r^2 c^2} \right) \quad (2)$$

In equation 2 the classical force is multiplied with a relativistic correction where $|r \times v|$ is the angular velocity and c is the light speed in vacuum.

ii. Forward euler method

Forward euler method is directly based on a taylor expansion to the first degree.

$$f(x+h) = f(x) + hf'(x) + \mathcal{O}(h^2) \quad (3) \quad F_x = -\frac{GM_\odot M_\bullet x}{r^3}, F_y = -\frac{GM_\odot M_\bullet y}{r^3}, F_z = -\frac{GM_\odot M_\bullet z}{r^3}$$

Using equation 3 to discrete values one get a numerical approximation of the next step based on the present information.

$$f_{i+1} = f_i + hf'_i + \mathcal{O}(h^2) \quad (4)$$

Where $x \rightarrow x = x_0 + ih$ and $f_i = f(x_i)$. This is an example of a stiff explicit equation. Since the equation is explicit, only a interval of steplengths are suited with respect to accuracy.

iii. Verlet velocity method

Verlet velocity method uses forward euler method as a fundament, but introduces a new taylor expansion of the velocity $v'(x)$.

$$v'(x+h) = v'(x) + hv''(x) + \mathcal{O}(h^2)$$

While discretizing the variables and using the relation $a(x) = v'(x)$, v''_i may be expressed using a_i and a_{i+1} .

$$v''_i = \frac{a_{i+1} - a_i}{h} + \mathcal{O}(h)$$

Inserted into a discretized second order taylor expansion of $v(x)$, an expression for v_{i+1} is achieved.

$$v_{i+1} = v_i + h \frac{a_{i+1} + a_i}{2} + \mathcal{O}(h^3) \quad (5)$$

A second order taylor expansion is also used to approximate x_{i+1} where $x'_i = v_i$ and $x''_i = a_i$

$$x_{i+1} = x_i + hv_i + \frac{h^2}{2} a_i + \mathcal{O}(h^3) \quad (6)$$

III. IMPLEMENTATION

Every planet in our solar system is affected by the gravitational force from the sun and other nearby planets. Where the gravitational force is

$$F_G = G \frac{M_\odot M_\bullet}{r^2} \quad (7)$$

where M_\odot and M_\bullet are the masses of two arbitrary objects. Decomposing the force into Cartesian coordinates, the components may be represented

$$F_x = -\frac{GM_\odot M_\bullet x}{r^3}, F_y = -\frac{GM_\odot M_\bullet y}{r^3}, F_z = -\frac{GM_\odot M_\bullet z}{r^3}$$

By Newton's second law the the relation between acceleration and position, we have the relation between the position of the planet and the total force component acting on the planet.

$$\frac{d^2x}{dt^2} = \frac{F_x}{M_\bullet}, \quad \frac{d^2y}{dt^2} = \frac{F_y}{M_\bullet}, \quad \frac{d^2z}{dt^2} = \frac{F_z}{M_\bullet}$$

Using the fact that Earth orbits the Sun in an almost circular motion [1], units of earth masses may be achieved by setting the centripetal force of the orbit equal to the gravitational force and solve for GM_\odot . Where M_\odot is the mass of the Sun.

$$GM_\odot = 4\pi^2 \frac{\text{AU}^3}{\text{Yr}^2} \quad (8)$$

Astronomical Units AU and years Yr are defined as the distance from Earth to the sun and the orbit time of Earth respectively. Equation 8 introduces Earth masses, Astronomical Units and Years as natural units for this system.

In total the system gets three sets of coupled differential equations per object in the system, which has to be solved to describe the system properly.

$$\frac{dx}{dt} = v_x \quad \wedge \quad \frac{dv_x}{dt} = \frac{F_x}{M_\bullet} \quad (9)$$

$$\frac{dy}{dt} = v_y \quad \wedge \quad \frac{dv_y}{dt} = \frac{F_y}{M_\bullet} \quad (10)$$

$$\frac{dz}{dt} = v_z \quad \wedge \quad \frac{dv_z}{dt} = \frac{F_z}{M_\bullet} \quad (11)$$

The system may be described with numerical methods by discretizing equations (9-11). Letting $t \rightarrow t_i = t_0 + ih, i \in \mathbb{N}$, $x \rightarrow x_i$ and $v \rightarrow v_i$ be the new discretized relations with the initial conditions $x(t_0) = x_0$ and $v(t_0) = v_0$ where x_0 and v_0 is known, and $h = \frac{t_{max}-t_0}{N}$. The equations may be solved by Euler's method resulting in an algorithm with an error $\mathcal{O}(h^2)$ at each calculation. Here $a_{k,i} = \frac{F_k(k_i)}{M_\bullet}$ where k represents an axis label.

```
x[i+1]=x[i]+h*xV[i]
y[i+1]=y[i]+h*yV[i]
z[i+1]=z[i]+h*zV[i]
xV[i+1]=xV[i]+h*xA[i]
yV[i+1]=yV[i]+h*yA[i]
zV[i+1]=zV[i]+h*zA[i]
```

Or with the more stable Verlet Vocity method reducing the error to $\mathcal{O}(h^3)$ for a calculation.

```
x[i+1]=x[i]+h*xV[i]+0.5*h*h*xA[i]
y[i+1]=y[i]+h*yV[i]+0.5*h*h*yA[i]
z[i+1]=z[i]+h*zV[i]+0.5*h*h*zA[i]
xV[i+1]=xV[i]+0.5*h*h*(xA[i+1]+xA[i])
yV[i+1]=yV[i]+0.5*h*h*(yA[i+1]+yA[i])
zV[i+1]=zV[i]+0.5*h*h*(zA[i+1]+zA[i])
```

These algorithms were implemented in a script that simulates the dynamics of the Sun and Earth.

All code and results are found in the GitHub repository

IV. RESULTS AND DISCUSSION

Table 1: Table showing the three lowest computed eigenvalues λ with N mesh points, compared to the exact $\lambda_0 = 3, \lambda_1 = 7$ and $\lambda_2 = 11$.

N	λ_0	λ_1	λ_2
10	2.68672	6.11302	11.0574
50	2.98745	6.93692	10.8453
100	2.99687	6.98432	10.9617
200	2.99916	6.99610	10.9904
300	2.99961	6.99828	10.9958
400	2.99986	6.99903	10.9976
500	2.99993	6.99937	10.9986
